#### Abstract

In the $\mathrm{L}-\mathrm{Arg}+\mathrm{HNO}_{3}+\mathrm{H}_{2} \mathrm{O}$ system, where Arg stands for arginine $\left({ }^{+}\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{CNH}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}\left(\mathrm{NH}_{2}\right) \mathrm{COO}^{-}\right)$, crystals of 2( $\mathrm{L}-$ Arg. $\mathrm{HNO}_{3}$ ) $\cdot \mathrm{H}_{2} \mathrm{O}$ (or formal L-Arg $\cdot \mathrm{HNO}_{3} \cdot 0 \cdot 5 \mathrm{H}_{2} \mathrm{O}$ ) (I) and L-Arg. $2 \mathrm{HNO}_{3}$ (II) compounds have been produced. The structures of both compounds were solved by X-ray crystallography. The asymmetric part of the triclinic unit cell (space group P1) of the (I) compound contains two monocharged arginine cations $\left(\mathrm{Arg}^{+}\right)$, two nitrate ions and a water molecule interacting through hydrogen bonds. The monoclinic unit cell of the (II) compound (space group $P 2_{1}$ ) is composed of two crystallographically independent nitrate ions and one doubly charged arginine cation hydrogen bonded to nitrate groups. The $\mathrm{Arg}^{+}$cations are hydrogen bonded to each other, while the $\mathrm{Arg}^{2+}$ cations do not interact. In addition the crystal of compound (II) emits phase matched second harmonic generation signal of a Nd:YAG laser. © 2003 Elsevier B.V. All rights reserved.

Keywords: Semiorganic NLO crystals; L-arginine nitrate; L-arginine dinitrate; Crystal structure

## 1. Introduction

The discovery of promising nonlinear optical properties in L-arginine phosphate monohydrate ( $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{H}_{3} \mathrm{PO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$, LAP) [1] and in its deuterated analog [2,3] stimulated a strong interest in the crystals of this family. In order to widen the understanding of LAP properties and to discover crystals with better nonlinear, mechanical and thermal properties, investigations on LAP analogs are in progress. The widest search for such crystals with interesting results were performed by Monaco et al. [4], who investigated known crystalline salts of $\mathrm{L}-\operatorname{arginine}$ ( $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HCl}$, $\mathrm{L}-$ Arg $\cdot \mathrm{HCl} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HBr} \cdot \mathrm{H}_{2} \mathrm{O}$ ) and as well prepared some new ones ( $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HF}$, $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HClO}_{4}$, $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HBF}_{4}$, $\mathrm{L}-$ Arg-malate, L - $\mathrm{Arg} \cdot 2 \mathrm{H}_{3} \mathrm{AsO}_{4}$ ). In addition and independently from Suresh and Vijayan [5] L-Arg. $\mathrm{CH}_{3} \mathrm{COOH}$ was synthesized and investigated. In Ref. [4] the compounds were prepared by evaporation at ambient temperature of aqueous solutions containing equimolar quantities of $\mathrm{L}-$ arginine and corresponding acids. Together with these

[^0]compounds obtained in crystalline form, they synthesized five other compounds in a form of noncrystalline fine powder (L-Arg-iodate, L-Arg•nitrate, L-Arg•formate, LArg.glutamate, L-Arg-aspartate). The authors did not clarify whether the glutamic and aspartic acids were in optically active form, or they exist as a racemate. In slightly different conditions (slow diffusion of different precipitants into aqueous solutions of arginine and acids), Vijayan with coworkers grew crystals of L-Arg•L-glutamate• $\mathrm{H}_{2} \mathrm{O}$ [6], L-Arg•D-glutamate $3 \mathrm{H}_{2} \mathrm{O}$ [7], L-Arg•D-glutamate• $\mathrm{H}_{2} \mathrm{O}$ [8], L-Arg-L-aspartate [9] and L-Arg.D-aspartate [7]. From three other compounds obtained by Monaco et al. [4] as powders, crystals of L-Arg. $2 \mathrm{HIO}_{3}$ and L-Arg. $2 \mathrm{HNO}_{3}$ [10,11] were grown for iodate and nitrate salts of arginine. In the attempts to grow crystals of the same composition for formate from solutions of $\mathrm{L}-\mathrm{Arg}+n \mathrm{HCOOH}$ with $n \geq 2$, crystals of $\mathrm{L}-$ Arg. HCOOH in space group $P 2_{1} 2_{1} 2_{1}$ were obtained [11]. Previously [12] another modification of L-Arg. HCOOH in space group $P 2_{1}$ from the aqueous solution of arginine and formic acid by slow diffusion of acetonitril was prepared. This raised hopes that from aqueous solutions of L Arg $+n \mathrm{HNO}_{3}$ with $1<n<2$ crystals of nitrate of arginine could be grown and indeed they were justified. This paper describes crystal structures of two L-arginine nitrate compounds grown by us.

## 2. Experimental

Crystals of nitrate and dinitrate salts of arginine were grown by evaporation of aqueous solutions. Phases were identified by IR spectra that were recorded by the method of suspension in nujol. Thermal properties were measured on a Paulik-Paulik-Erdey derivatograph and on a Boëtius type microscope equipped with a heated table. A Q-switched

Nd:YAG laser was used to detect existence of second harmonic generation signals. Room temperature X-ray diffraction data were collected on an Enraf-Nonius CAD4 diffractometer. Statistics on the data are given in Table 1. The structures were solved and refined employing program suites SHELXS-97 and SHELXL-97 [13,14]. The positions of all hydrogen atoms were determined from difference Fourier maps and were refined with isotropic thermal parameters.

## 3. Results and discussion

From the aqueous solution containing equimolar quantities of L-arginine and nitric acid only an apparently noncrystalline powder could be obtained. Needle like crystals were grown from aqueous solution containing Larginine and $\mathrm{HNO}_{3}$ in 1:1.25 ratio. It is important to mention that the IR absorption spectra of these crystals and the powder were identical. Thermal analysis showed that above $90^{\circ} \mathrm{C}$, a sample mass loss of about $2.5 \%$ takes place accompanied by an endothermic effect. Further heating results in decomposition of the sample above $200^{\circ} \mathrm{C}$. From this, an assumption could be made that the sample was a hydrocrystal. The mass loss of $2.5 \%$ corresponds to $n=0.4$ water molecules. But comparison of IR spectra of initial and heated at $130^{\circ} \mathrm{C}$ samples (see Fig. 1) did not show any absorption band above $3000 \mathrm{~cm}^{-1}$ that disappears during heating. Thus IR spectra and thermal analysis did not allow us to identify with confidence the existence and quantity of crystallization water molecules. Nevertheless the crystal structure determination revealed that nitrate of L -arginine is a hydrocrystal of $2\left(\mathrm{~L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3}\right) \cdot \mathrm{H}_{2} \mathrm{O}$ (or formally L $\left.\mathrm{Arg} \cdot \mathrm{HNO}_{3} \cdot 0.5 \mathrm{H}_{2} \mathrm{O}\right)$ composition.

Growth conditions and preliminary data on LArg. $2 \mathrm{HNO}_{3}$ were represented in Ref. [11]. In Table 1, the crystallographic data and details of structure determination and refinement for $2\left(\mathrm{~L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3}\right) \cdot \mathrm{H}_{2} \mathrm{O}$ (I) and L Arg. $2 \mathrm{HNO}_{3}$ (II) are represented. Further tables with even numbers correspond to structure (I), while those with odd numbers correspond to structure (II). Coordinates of atoms are represented in Tables 2 and 3. In Fig. 2 asymmetric unit cells and numbering of atoms for both structures are illustrated. Bond lengths and angles are collected in Tables 4 and 5, while Tables 6 and 7 represent hydrogen bond parameters. In the selection of intermolecular hydrogen bonds we followed the recommendations of Zefirov [15]
declaring that for $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ type bonds the $\mathrm{H} \cdots \mathrm{O}$ distances of strongest van der Waals and weakest hydrogen bonds lie in the range $2.45-2.15 \AA$.

The unit cell of (I) contains one formula unit composed of two ions of $\mathrm{NO}_{3}^{-}$, two cations of $\mathrm{L}-\mathrm{Arg}^{+}$and one crystallization water molecule. The bond lengths for $\mathrm{C}-\mathrm{O}$ are typical for negatively charged carboxylate groups. The guanidyl and $\alpha$-amino groups are protonated, as is usual for L- $\mathrm{Arg}^{+}$. The bond lengths in cations are typical as well, except for $\mathrm{C}(6 \mathrm{~B})-\mathrm{N}(3 \mathrm{~B})$, which is shorter than the expected value of $1.32 \AA$. A characteristic feature of L-arginine cations is their interaction with each other through hydrogen bonds, as they contain a negatively charged carboxylate group and positively charged protonated guanidyl and $\alpha$ amino groups. The hydrogen bonds between $\alpha$-amino groups and oxygen atoms of corresponding carboxylate groups $\mathrm{N}(1 \mathrm{~A})-\mathrm{H}(1 \mathrm{~A}) \cdots \mathrm{O}(1 \mathrm{~A})$ and $\mathrm{N}(1 \mathrm{~B})-\mathrm{H}(1 \mathrm{~B}) \cdots \mathrm{O}(1 \mathrm{~B})$ are strong, while weaker ones connect guanidyl groups $\mathrm{N}(3 \mathrm{~A})$ and $\mathrm{N}(3 \mathrm{~B})$ with atoms $\mathrm{O}(2 \mathrm{~A})$ and $\mathrm{O}(2 \mathrm{~B})$, respectively. A water molecule acting as an acceptor, binds to both cations by hydrogen bonds $(\mathrm{N}(1 \mathrm{~A})-\mathrm{H}(3 \mathrm{~A}) \cdots \mathrm{O}(1 \mathrm{~W})$ and $\mathrm{N}(4 \mathrm{~B})-\mathrm{H}(14 \mathrm{~B}) \cdots \mathrm{O}(1 \mathrm{~W}))$ and as a donor to two symmetrically equivalent cations of second type through $\mathrm{O}(1 \mathrm{~W})-$ $\mathrm{H}(2 \mathrm{~W}) \cdots \mathrm{O}(1 \mathrm{~B})$ and $\mathrm{O}(1 \mathrm{~W})-\mathrm{H}(1 \mathrm{~W}) \cdots \mathrm{O}(2 \mathrm{~B})$. In addition the $\mathrm{O}(2 \mathrm{~A})$ oxygen atom of the first cation is hydrogen bonded to $\alpha$-amino group of the second cation. The rest of hydrogen bonds (quite weak) connect cations with $\mathrm{NO}_{3}^{-}$ ions. Two of these hydrogen bonds (N(4A)$\mathrm{H}(15 \mathrm{~A}) \cdots \mathrm{O}(3 \mathrm{~B})$ and $\mathrm{N}(3 \mathrm{~B})-\mathrm{H}(12 \mathrm{~B}) \cdots \mathrm{O}(3 \mathrm{~A})$ ) have $\mathrm{H} \cdots \mathrm{O}$ distances almost at the edge of above mentioned range and their angles significantly differ from $180^{\circ}$. Corresponding $\mathrm{N}-\mathrm{O}$ bonds were expected to be shorter but that is true only for the $\mathrm{N}(5 \mathrm{~A})-\mathrm{O}(3 \mathrm{~A})$ bond. The data on hydrogen bonds allows estimation of the range of the frequencies for stretching vibrations $\nu(\mathrm{O}-\mathrm{H})$ and $\nu(\mathrm{N}-\mathrm{H})$. Vibration frequencies for water molecules $\nu(\mathrm{O}-\mathrm{H})$ in

Fig. 2. Asymmetric unit cells of (a) $2\left(\mathrm{~L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3}\right) \cdot \mathrm{H}_{2} \mathrm{O}$ and (b) $\mathrm{L}-$ Arg. $2 \mathrm{HNO}_{3}$.
the difficulty in the determination of $\nu(\mathrm{O}-\mathrm{H})$ for water from IR spectra of $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3} \cdot 0.5 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3}$ (see Fig. 1) was caused by this phenomenon. The packing of molecules in the structure of $2\left(\mathrm{~L}-\mathrm{Arg} \cdot \mathrm{HNO}_{3}\right) \cdot \mathrm{H}_{2} \mathrm{O}$ is shown in Fig. 3a.

In the second structure, $\mathrm{L}-\mathrm{Arg} \cdot 2 \mathrm{HNO}_{3}$, the asymmetric unit cell contains doubly charged cation of arginine ( $\mathrm{L}-$ $\mathrm{Arg}^{2+}$ ) and two $\mathrm{NO}_{3}^{-}$ions. The difference between cations $\mathrm{L}-\mathrm{Arg}^{2+}$ and $\mathrm{L}-\mathrm{Arg}^{+}$is that, in the case of $\mathrm{L}-$ $\mathrm{Arg}^{2+}$, as a result of additional protonation of carboxylate group, there is an uncharged carboxylic group. $\alpha$-Amino and guanidyl groups similar to the case of $\mathrm{L}-\mathrm{Arg}^{+}$, are protonated. The existence of a doubly charged cation L$\mathrm{Arg}^{2+}$ was first discovered by Seely [18] in L-Arg.2HI. The presence of neutral carboxylic group results in significant differences between hydrogen bonding in salts of $\mathrm{L}-\mathrm{Arg}^{+}$and $\mathrm{L}-\mathrm{Arg}^{2+}$, particularly (I) and (II). One of the $\mathrm{NO}_{3}^{-}$ions is bonded to cation of $\mathrm{L}-\mathrm{Arg}^{2+}$

the guanidyl group are significantly weaker. The bond lengths for some of them are close to the upper edge of the range and $\mathrm{N}(3)-\mathrm{H}(13)$ do not form any hydrogen bond. Among the bonds in the nitrate ions, the shortest is the bond $\mathrm{N}(5)-\mathrm{O}(5)$ because of the weakness of hydrogen bonds established by the $\mathrm{O}(5)$ atom, as well as the bond $\mathrm{N}(6)-\mathrm{O}(7)$. Here oxygen $\mathrm{O}(7)$ does not have hydrogen bonds. The strongest hydrogen bonds $\mathrm{O}(2)-\mathrm{H}(1) \cdots \mathrm{O}(4)$ and $\mathrm{N}(1)-\mathrm{H}(3) \cdots \mathrm{O}(8)$ slightly elongate the corresponding bonds $\mathrm{N}(5)-\mathrm{O}(4)$ and $\mathrm{N}(6)-\mathrm{O}(8)$. The important difference between structures (I) and (II) is that $\mathrm{L}-\mathrm{Arg}^{+}$cations interact with each other via hydrogen bonds while L$\mathrm{Arg}^{2+}$ do not. This peculiarity, which apparently is general for salts of $\mathrm{L}-\mathrm{Arg}^{2+}$ with oxygen containing anions, was mentioned in Ref. [19] for L-Arg. $2 \mathrm{H}_{3} \mathrm{PO}_{4}$ and for isotypical L-Arg. $2 \mathrm{H}_{3} \mathrm{AsO}_{4}$. On the basis of the data on hydrogen bonds in L -Arg. $2 \mathrm{HNO}_{3}$, correspondence between high frequency absorption bands in the IR spectrum of L-Arg. $2 \mathrm{HNO}_{3}$ [11] and its groups could be
refined. For example, the absorption band $\nu(\mathrm{O}-\mathrm{H})$ proceeding from correlation between the $\nu(\mathrm{O}-\mathrm{H})$ and $\mathrm{O} \cdots \mathrm{O}$ distance is in the $3000 \mathrm{~cm}^{-1}$ region, while absorption bands of $\nu(\mathrm{N}-\mathrm{H})$ occupy the 3100$3500 \mathrm{~cm}^{-1}$ range. The highest frequency bands must be related to vibrations of the $\mathrm{N}(3) \mathrm{H}_{2}$ group, in which bond $\mathrm{N}(3)-\mathrm{H}(13)$ is free and does not form hydrogen bonds. Fig. 3b displays the crystal packing for $\mathrm{L}-\mathrm{Arg} 2 \mathrm{HNO}_{3}$ showing only strongest hydrogen bonds. Heating of $\mathrm{L}-$ Arg. $2 \mathrm{HNO}_{3}$ causes melting of the sample around $130^{\circ} \mathrm{C}$ (DTA peak at $135^{\circ} \mathrm{C}$ ) and its decomposition with exothermal effect at temperatures above $160^{\circ} \mathrm{C}$. Our first crystals of L-Arg. $2 \mathrm{HNO}_{3}$ had the shape of thin plates. Later we grew optical quality crystals of $33 \times 10 \times 5 \mathrm{~mm}^{3}$ size, in which phase matched second harmonic generation of Nd:YAG laser was obtained.

After publication of our preliminary data [11] on the L-Arg. $2 \mathrm{HNO}_{3}$ crystal structure, Ramaswamy et al. [20] also determined the structure of L-Arg- $2 \mathrm{HNO}_{3}$.

| N4-H16 $\cdots$ O6 | $x, y, z$ | 2.978 | 0.87 | 2.13 | 165.2 |

Fig. 3. A stereoview of the crystal packing in (a) 2(L-Arg• $\left.\mathrm{HNO}_{3}\right) \cdot \mathrm{H}_{2} \mathrm{O}$ and (b) L-Arg. $2 \mathrm{HNO}_{3}$. Hydrogen bonds are shown by dashed lines. In structure of L-Arg- $2 \mathrm{HNO}_{3}$ only strongest hydrogen bonds are shown.

In spite of difference in $R$-factors (0.031 and 0.070, respectively) (with the exception of one $\mathrm{C}-\mathrm{N}$ bond length in guanidyl group) results are in good accordance.
